

My OPPW TQQQ Trading Strategy:

IT'S YOUR FINANCIAL FUTURE

by: Guy R. Fleury

My previous article: [YOUR MULTI-MILLION DOLLAR QUEST](#), showed some of the strategy's potential and ended with a call to further improve it. Places where the program could be improved were also provided.

Using my strategy's portfolio equation, I made projections and estimates for the next 20 years, providing a starting point for further research and enhancements that would lead to even higher performance. Here is a chart from my November 24, 2025, article cited above.

Figure #1: My OPPW TQQQ Portfolio Simulation Metrics. 15.7 Years.

Those results already exceed expectations for anyone following traditional portfolio management methods. The program does not follow diversification principles, even if it does indirectly. Nor does it follow MPT (Modern Portfolio Theory), as if it skipped over or ignored it entirely.

Underlying everything in this strategy, you are playing on the average price movements of the top 100 most valuable stocks on the NASDAQ exchange. TQQQ is a 3x-leveraged version of QQQ. For any 2% move in QQQ, we expect a 6% change in the price of TQQQ. We have a 3x leveraged QQQ scenario that amplifies its price swings.

The foundation of my trading strategy rests on QQQ. It will be around for many years. You are not dealing with one stock, but with the top 100 of the highest valued stocks with a combined value in excess of \$20 trillion. In 20+ years from now, you will still have 100 stocks in QQQ, no matter how many changes time will make to the list.

The collective value of those 100 QQQ stocks in 20 years could be near \$130 trillion should they increase at an average 10% growth rate. Those stocks will do better than that; even the slowest of the group will do better. Otherwise, they would not be part of the list.

A criticism I often hear is that these strategy results are impossible. No trading strategy operates at these high CAGR levels. So, it must be hype.

I certainly disagree with that. Nonetheless, such a statement could hold if it were some secret sauce for some fantastic proprietary trading system, with no concrete proof, and where you have to pay unprecedented fees to be part of it, as in so many scams we see in the market.

Whereas here:

*I published my free program code in mid-November 2024 to go along with my paper: **Gain Your Financial Freedom**. That is over a year ago. Anyone can verify Figure #1 above by running the program. It should be sufficient to show that Figure #1 is real and not some hype. To get Figure #1, you would need to add the small program changes proposed during the year.*

The reason I do not provide my latest program version is simply that I want everyone using this strategy to have different exit points. And to get this, we need different trading procedures that will reach about the same overall objective.

There are a multitude of ways to add worthwhile routines to this trading strategy. My published version will reach the mid-50% CAGR. Figure #1 above only shows some of the strategy's potential, with its 77.80% CAGR.

My program depends on the volatility of QQQ. It treats QQQ's price variations as a quasi-random series of events and accepts to gamble on that volatility.

My strategy makes no predictions, does not follow technical indicators or sentiment analysis, and ignores all fundamental data, past, present, or future. We are facing raw uncertainty. In other words, it is like facing a quasi-50/50 proposition (like the flip of a coin). We are always at the right edge of the price chart.

Even with years of statistical data to provide averages, linear regressions, correlations, and volatility measures, we cannot put odds on the next move. Even with that data, we cannot say that the price will rise tomorrow with a 70% probability. Those who tried soon found it was not an especially effective way to succeed.

Most market participant extended their "forecasting" horizon to years to slightly improve their hit rates, leaving day forecasts to tipsters and hypesters, with whatever claims they made.

It will be your money on the line, and you certainly do not want to lose. You find yourself at the center of it all. You know the stock market is risky, but here, it appears riskier not to participate, to forego the potential benefits this trading strategy can bring you. As I have stated many times, you are in control, from A to Z. Your stock portfolio is part of your trading account, under your control and accessible only by you.

You will need the confidence in yourself to carry it out for years to come. I wrote about my OPPW strategy so you could explore what it can do and determine if it would be appropriate for you. My articles will help you better understand what it could also do for you.

You can gain that confidence by proving to yourself that what is presented not only held over the past 15.7 years, but will hold for the next 20. Without this confidence, why take up that 20-year quest?

It becomes elementary: you should not only understand what the strategy can do, but also accept what it does in its trading environment, and that randomness will play a significant role. If you cannot convince yourself that what you intend to do will work, how could you apply it and risk losing some of your capital?

My latest version of the OPPW TQQQ strategy will make at least one bet every week, facing a quasi-random outcome. Your trading account will be in cash at the end of every trading week.

We take the trade with no knowledge of its outcome. You could call it a one-week investment, but it is just a bet. What you know is that no matter how quasi-random the price series might be, by consistently betting on the same side, you will catch whatever underlying edge there might be in the price series. If the price series has a 52/48 likelihood, that is what your betting system will get since you are always betting on the same side.

You did nothing special; you just made your bet every week and got the 52/48 outcome. This is not a big edge. You win, and it is almost without merit. Regardless, money is money, and if I can realize Figure #1 within some 20 years, all I can say is: thanks, and you can do it too.

You cannot save yourself from doing the work. As mentioned in prior articles, there is no free lunch in the market. Every penny you make, you will have to earn it, and you will have deserved it. My OPPW trading strategy has a built-in edge due to its trading procedures, which will make a real difference.

You will have played the game under the same trading rules as everybody else: no scheme, no scam, just honest purchases and liquidations at the time of your choosing. You transferred your discretionary trading methods to a program. It works, as it should. Being automated, your strategy will require little of your time.

We all have to consider the nature of risk. Not necessarily market risk, but certainly our view on what constitutes portfolio risk. Being in cash represents no risk. But it is also non-productive. If you take a trade, and it falls by -10% to then recover back to the same price, what was your risk? Was it worth waiting for the price to recover?

It is only if we accept to sell at -10% that we will realize our loss and make it permanent. But, if you do not sell and it recovers, you no longer have a loss to show or endure. It is not the market loss that is bothering you; it is your portfolio loss, no matter its origin.

You want return stability? You will not get it playing the stock market game. You should be looking for long-term growth rates that exceed market-average proxies. That can be delivered, with all its ups and downs, over the years ahead. The longer you stay, the better your odds of succeeding. The odds of finishing ahead asymptotically approach 1.00 as time nears 20+ years, and almost surely 1.00 beyond those 20 years.

The point is this trading strategy will take time, not much of your personal time (5-10 minutes per week), but elapsed time (some 20+ years). These are things you should consider before undertaking such a journey, even if you know it will be beneficial to your trading and retirement account.

Table #1 below presents ordered expected long-term growth rates. You can pick the growth rate level you want or can bear. If you are satisfied with SPY, that is fine. But do not expect that scenario to deviate much from its 10% average long-term CAGR.

You can reach all the OPPW TQQQ levels. Two levels have published program code (35%, and 55%). Higher levels will require program modifications to access them. Nonetheless, they are reachable. It goes like this: if I can do it, you can do it too.

Table #1: Long-Term Return Expectations (Pick One).

Initial Capital	Growth Rate (%)	# Years	Portfolio Value (\$)	Available From

100,000	85%	20	22,051,318,804	WL User #3 Mod5 ^{2,3}
100,000	87%	20	27,342,116,582	Fleury's OPPW 2.1
100,000	? %	20	?	WL User #3 Mod7+ ^{2,3}
100,000	? %	20	?	? YOU ?

These are rough estimates and should be viewed as such.

¹ Berkshire Hathaway's CAGR has been more in the 13% range over the last 15 years.

² Users #1, #2, and #3 are Wealth-Lab members who have shown their simulation results.

³ WL users' names withheld due to privacy concerns.

You can pick any level you want. The only restricted level is the Medallion Fund, which is available only to Renaissance Technologies' senior management.

The program version of User #1, just as mine (my OPPW version 1.0), is in the public domain. Anyone can copy the program code and put it to good use. As for my other versions, we can see the progression, step by step, that led to higher CAGRs. You can find a description of my code modifications in my articles. Anyone could easily duplicate and incorporate them into their version to achieve similar results.

Some people do even better than my version 2.0, which is commendable. I congratulate them on a job well done.

It was the whole purpose of why I published so many articles on this trading strategy so people could understand it, modify it, and make it their own. Anyone could do even better. There is much potential to extract from the guiding principles of this trading strategy. Can YOU push this trading strategy even higher, CAGR-wise? I believe you can.

Since my OPPW TQQQ trading strategy is 100% scalable, perhaps the easiest way to increase the outcome is to invest more initial capital. For example, putting \$200k on my version 2.0 would add another \$12.7 billion to the trading account over those 20 years, making the quest for that added \$100k more than worthwhile. Like in everything else, it is all up to you.

– ON DOING BETTER

After adding a few lines of code, the program generated Figure #2.

Figure #2: My OPPW TQQQ Portfolio Simulation Metrics. 15.7 Years.

([Click here to enlarge](#))

We can easily see the increase. The CAGR went from 77.80% to 81.11%. It might not appear as a big move. But still, we have a difference of \$304,950,192 over the same time interval due to a slight change in the program code.

For having added a few lines of code, the strategy could give back some \$304 million more. Would you do the program changes?

Anyone can improve their trading program. This one is rather special. It gambles its way to riches, exploiting its slight built-in edge — an edge provided by the trade mechanics applied to the game. With each trading procedure, we can amplify those outcomes, even if we do not know what the next trade will yield. We play for long-term averages, long-term return averages at that.

The strategy makes a bet every week, regardless of its past or future. It always bets that prices will go up. If the price does not rise, the strategy will take the loss.

No technical indicators or fundamental data are making those trading decisions. All trades start with the price at Monday's open and go from there, following its set of trading rules.¹ As often mentioned before, it is like always betting on heads on every flip of a coin. You should get something close to 50/50, unless you have a slight edge. Something like 52/48, for instance. The strategy is not asking much. It makes most of its money through its trade mechanics and simple trading procedures.

Quasi-random trading programs have not, in the past, proven able to survive over extended time intervals or deliver high long-term returns. And yet, this one does. Not only that, it thrives. It even exhibits a rising CAGR with time. Refer to Figure #4 in the above-cited article, where an estimate is made based on the long-term trading statistics and portfolio metrics of the strategy.²

Figure #2 shows an 81.11% CAGR, which is outstanding, if not phenomenal. It supersedes the vast majority of stock trading strategies. And, it does it over 15.7 years. Nonetheless, anyone could do better with additional trading procedures, as suggested in my prior articles and in Table #1 above.

Understandably, since we are trading TQQQ, a 3x-leveraged ETF, we should have expected returns above market averages. TQQQ, if held over the past 15.7 years, would have generated a 41% CAGR, but with a -81% drawdown, which no one wants to bear. Note that both charts above have TQQQ as a benchmark.

In Figure #2, the drawdown improved from -48.46% to -37.93% as the overall CAGR rose from 77.80% to 81.11%. Even SPY, over the same interval, had a -34.10% drawdown.

To reduce the drawdown by 3.83%, would you accept SPY's 12.21% CAGR? What we have is the maximum drawdown, which lasted only one day over a 15.7-year trading interval. Could you not withstand that extra 3.83% single-day drawdown for a billion dollars?

Under MPT (Modern Portfolio Theory), you cannot get such results. The 15.7-year

¹ These have been given in prior articles.

² That chart is replicated below as Figure #3.

81.11% CAGR is way beyond what you could expect from MPT. If there was an efficient frontier that would limit your performance, you jumped over it without even giving it a second glance.

The big question should be: Will the US stock market have about the same volatility in the future? There is no reason to think it will be different than over the past 200+ years. The market will remain unpredictable with its highs and lows. We will still have to navigate a tumultuous sea of variance.

– **SO, WHAT CHANGED?**

Getting \$304,950,192 more by changing a few lines of code, I'm ready to listen.

The program's core trading procedures remained unchanged. Each Monday, at the open, a position is taken and sold by Friday's close. This procedure has been in place since my first article in the series on this trading strategy (May 2024). We have two types of trades liquidated at Friday's close: Type-B and Type-D.³

All Type-B trades will close with a profit of less than 7%, while all Type-D trades will finish at a loss. We have two of the four trade types that operate as if in a buy-and-hold position for the trading week.

The liquidation at Friday's close will leave the trading account in cash over all weekends. Your participation in the market is limited to 5 trading days at a time. Each bet is independent of all others, but each will build on previous trades. We have a compounding trading environment.

My portfolio equation as used in my previous article⁴ is repeated here:

$$\mathbb{E}[FV] = 0.5590 \cdot 100000 \cdot (1 + 0.04444)^{486} \cdot (1 - 0.027883)^{406} = 867,995,202 \quad (1)$$

It relates to the portfolio metrics we see in Figure #1.

As for Figure #2, with small metric adjustments, the equation becomes:

$$\mathbb{E}[FV] = 0.5247 \cdot 100000 \cdot (1 + 0.03944)^{515} \cdot (1 - 0.02621)^{373} = 1,172,670,348 \quad (2)$$

where the parameters have the same meaning. Both equations use their respective portfolio metric results.

Equation (1) had 486 winning trades and 406 losing trades for a total of 892. Whereas equation (2) had 515 winning and 373 losing trades totaling 888 over the same 15.7 years.

³ For a description of the trade types, refer to [A WINNING EXAMPLE](#).

⁴ Refer to [YOUR MULTI-MILLION DOLLAR QUEST](#)

Equation (2) got more winning trades and fewer losing trades, while the winning trades have a smaller average percent win per winning trade. We also have a lower average percent loss per losing trade. It can explain part of the difference in the gaming procedures.

Both equations are variations of my general portfolio equation for this trading strategy. Here it is again:

$$F(t) = \bar{e} \cdot f_0 \cdot (1 + \bar{r}_+)^{N-\lambda} \cdot (1 - \bar{r}_-)^{\lambda} = f_0 \cdot (1 + \bar{g}_N)^N \quad (3)$$

where $\bar{r}_+$ is the average percent win per winning trade, $\bar{r}_-$ is the average percent loss per losing trade, λ is the number of losing trades, N is the total number of trades, and $\bar{e}$ the strategy's average exposure rate. All those numbers come from the strategy's portfolio metrics.

The equations give the same answer as using the strategy's average return $\bar{g}_N$, the average percent return per trade.

We are interested in the evolution of equation (3), as it accounts for both winning and losing trades. Equation (3) will become a better estimator of its future as the number of trades increases, or as the average percent per winning or losing trades tends to their long-term averages.

If we change the program's trading rules, we should expect to see the impact on the strategy's past price data. But also, on the strategy's future development. The trading strategy should continue with the same trading habits it acquired in the past. And as the number of trades increases in the hundreds, it will become a better and better representation of what we could anticipate as ballpark future estimates for this trading strategy.

What is the difference between equations (1) and (2)?

The changes result from the trading decisions made.

My program is still operating using the same core trading procedures. We should have had about 820 trades over the period (one per week). We now have 892 trades in Figure #1 and 888 in Figure #2. The strategy added 72 and 68 trades to those two simulations. However, the difference in the number of trades is not sufficient to explain the difference in their outcomes.

As suggested in **YOUR MULTI-MILLION DOLLAR QUEST** (Nov. 24), we added new trades to the mix. Once a trade was closed early in the week (Type-A or Type-C), the program could initiate another trade with a lower profit target. This procedure aimed to increase the number of profitable trades. You would not win all the added trades, but that was not the point. The strategy's outcome was: did it result in more profits?

Both trade types (Type-A and Type-C) are executed on rising prices, whether to reach a profit target or as a rebound from a loss. And since we are relatively poor at guessing those exit prices, we could easily understand that the prices would not turn back down after exiting the trade. Therefore, taking a new trade on rising prices following an exit could be a profitable proposition on average. Some 90+% of trades will exceed their exit targets. Not adding a new trade is like leaving money on the table. It is, nonetheless, a choice you can make or not.

We still maintained an edge. With the new trading rules, we accepted a lower average percent win per winning trade by accepting a lower return on those new trades, which, when combined, would result in a lower average percent win per winning trade.⁵ A closing procedure was also added as a break-even stop-loss for trades that have exceeded a profit of 2.5%. This procedure tended to reduce potential losses.

Part of the strategy's improvement comes from reducing negative trades by accepting a stop-loss on bad trades (Type-D). It tended to decrease the average percent loss per losing trade, which was beneficial to the overall result, as shown in equation (2). At the same time, we saw fewer losing trades.

The prevailing equation in all this is the second part of equation (3): $f_0 \cdot (1 + \bar{g}_N)^N$, which reduces everything to a simple compounding equation based on the average portfolio return. It does not matter how you will trade; the objective will remain to have $\bar{g}_N$ as high as possible.

Regardless, it is up to you to choose the CAGR level at which you would like to invest in the market. Most levels given in Table #1 are available with a couple of exceptions. Nonetheless, you could improve the trading strategy and outperform them all.

From Figures #1 and #2, we have $\bar{g}_N$ go from 1.15% to 1.17% per trade. It is not what could be called a major change, yet it accounts for the \$300 million improvement over those 15.7 years. That is what is at stake.

– IMPROVING THE FUTURE?

Is that possible? In the context of my OPPW TQQQ trading strategy: YES, and relatively easily. You improve the outcome of a software program, and it can make you millions. Why would you not make those changes?

Having improved the trading procedures,⁶ we now have improved portfolio metrics from which we can determine possible future outcomes — making new estimates to reflect the added trading procedures.

⁵ See equations (1) and (2).

⁶ Refer to equation (2).

Figure #4 in **YOUR MULTI-MILLION DOLLAR QUEST**, is reproduced below as Figure #3. The projections use the portfolio metrics in equation (1).

Figure #3: My OPPW TQQQ 20-year Estimate. Nov. 15, 2025

My OPPW TQQQ Estimates Based On WL Portfolio Metrics Simulation. Nov. 15, 2025.

15.7-year OPPW simulation: \$ 867,995,203 Profit. CAGR: 77.85%

1-year forward profit estimate:	\$	102,930	Expected CAGR:	2.93%
2-year forward profit estimate:	\$	189,528	Expected CAGR:	37.67%
3-year forward profit estimate:	\$	348,984	Expected CAGR:	51.68%
4-year forward profit estimate:	\$	642,594	Expected CAGR:	59.22%
5-year forward profit estimate:	\$	1,183,227	Expected CAGR:	63.91%
6-year forward profit estimate:	\$	2,178,709	Expected CAGR:	67.12%
7-year forward profit estimate:	\$	4,011,719	Expected CAGR:	69.45%
8-year forward profit estimate:	\$	7,386,893	Expected CAGR:	71.22%
9-year forward profit estimate:	\$	13,601,695	Expected CAGR:	72.61%
10-year forward profit estimate:	\$	25,045,188	Expected CAGR:	73.73%
11-year forward profit estimate:	\$	46,116,415	Expected CAGR:	74.65%
12-year forward profit estimate:	\$	84,915,464	Expected CAGR:	75.42%
13-year forward profit estimate:	\$	156,357,255	Expected CAGR:	76.08%
14-year forward profit estimate:	\$	287,905,051	Expected CAGR:	76.64%
15-year forward profit estimate:	\$	530,127,743	Expected CAGR:	77.13%
16-year forward profit estimate:	\$	976,139,262	Expected CAGR:	77.56%
17-year forward profit estimate:	\$	1,797,392,932	Expected CAGR:	77.94%
18-year forward profit estimate:	\$	3,309,590,626	Expected CAGR:	78.28%
19-year forward profit estimate:	\$	6,094,043,166	Expected CAGR:	78.58%
20-year forward profit estimate:	\$	11,221,134,668	Expected CAGR:	78.86%

The intention is to update that chart using the parameters of equation (2). We know it will have an impact since the equation is still an exponential function. And therefore, we should see the effect of compounding at a higher level.

The projections in Figure #4 used an initial price of \$50 for TQQQ (after the 2:1 split). Using the price before the split would change the price and expected trade volume. The profit and CAGR would remain the same, since the strategy plays on percentage returns rather than price. Furthermore, the strategy is 100% scalable due to its method of play.

To make the point, Figure #5 is the same chart, but with \$100 as the initial price for TQQQ (as if before the split).

Figure #5: My OPPW TQQQ 20-year Estimate. Nov. 21, 2025

([Click here to enlarge](#))

Those small procedural changes added some \$6 billion to the 20-year scenario. Yet, you only did minor changes to the code. All relatively reasonable moves requiring little added insight, nonetheless, commanding common sense as to what we can do.

With a long-term view of this trading strategy, even small changes to the set of trading rules can have long-lasting effects on its outcome. Figures #3 and #4 are a testament to that.

You would not need much to push the outcome even higher.

We could raise the average percent win per winning trade by 1%. It would give the following using equation (2):

$$\mathbb{E}[FV] = 0.5247 \cdot 100000 \cdot (1 + 0.03944 \cdot \underline{1.01})^{515} \cdot (1 - 0.02621)^{373} = 1,399,792,009 \quad (4)$$

This is over the same 15.7 years. Over the 20 years, it has the potential of adding some \$5 billion to the outcome.⁷ It is not a major shift in the trading procedures. It would increase the average percent win per winning trade from 3.944% to 3.983%.

Using equation (4) to generate the 20-year estimates gives Figure #6.

Figure #6: My OPPW TQQQ 20-year Estimate. Nov. 21, 2025

My OPPW TQQQ Estimates Based On WL Portfolio Metrics Simulation. Nov. 21, 2025.
 15.7-year OPPW: \$ 867,995,203 Profit. CAGR: 77.85% See Figure #1
 Starting price: \$50. + 1% increase in winning trades.

— THE COMPOUNDING THING

We are playing a compounding-return game with an unknown future, and depend on the weekly volatility of a 3x-leveraged ETF. The objective was to achieve an average return of 1

We can design trading rules that will follow our perception of the game. We might not have future odds on any of the trades we will make, but we do have statistics on how the strategy could have behaved in the past under uncertainty across hundreds of trades.

It is what those equations and charts are saying. If you want to win and win big, you have to play the long game. That is where the real money is. It is not a profitable trade here and there; it is the average outcome of all those trades over many years. Even more so, it will be the last few years that will matter the most, as you can see in Figures #3, #4, and #6. But to get those, you have to get there.

⁷ Compared to Figure #3.

In the beginning, whichever steps you take might not matter much. It is the continuous buildup, trade upon trade, that will make a difference. Your portfolio will go up and down over the years. But over the long term, your portfolio will keep rising, hitting new highs after new highs.

As I have said many times before, you can do even better. It is all up to you.

For example, if you wanted to improve the average percent win per winning trade by 2%, it would also impact the forward outlook. We could adapt equation (4) and increase its average percent win rate for winning trades by 2% to provide a ballpark estimate.

$$\mathbb{E}[FV] = 0.5247 \cdot 100000 \cdot (1 + 0.03944 \cdot \underline{1.02})^{515} \cdot (1 - 0.02621)^{373} = 1,701,033,405 \quad (5)$$

Would it not suggest that the quest to improve the average percent win per winning trade, even by 2%, is a worthwhile endeavor?

The move would push the average percent win per winning trade from 3.944% to 4.022%. It is not what you would call a big change. Nonetheless, that result will spread out over those years of weekly trading.

Why will this all hold up? That is easy. Over an extended time interval and with a large number of trades, we should expect that our trading strategy does something similar to what triggered its trades in the past, should those conditions prevail in the future.

It goes back to equation (3). Here it is again:

$$F(t) = \bar{e} \cdot f_0 \cdot (1 + \bar{r}_+)^{N-\lambda} \cdot (1 - \bar{r}_-)^{\lambda} = f_0 \cdot (1 + \bar{g}_N)^N$$

where we defined the total number of trades as N .

The objective is to reinterpret that equation by breaking it down into what happened up to the end of our simulation date and what happens after. So, I propose this other Fleury equation:

$$F(t) = f_0 \cdot \prod_{i=1}^k (1 + r_i) \cdot \prod_{k}^N (1 + r_i) = f_0 \cdot (1 + \bar{g}_k)^k \cdot (1 + \tilde{g}_N)^N \rightarrow f_0 \cdot (1 + \bar{g})^N \quad (6)$$

where we have k trades by the end of the simulation, and $N - k$ future trades representing the future trades of the trading strategy. It would be like in Figure #3, where k was equal to 892 trades over the first 15.7 years, and $N - k$ would stand for all the trades after the 15.7 years up to year 20.

The expectation is that: $\bar{g}_k \rightarrow \tilde{g}_N$. It would be sufficient to expect that the future will resemble the past. And the same long-term trade metrics could hold going forward.

Equation (6) might look complicated, but it is nevertheless a simple expression that can attest to the projections and justify the estimates we made. Furthermore, those long-term averages will become increasingly statistically significant as the number of trades in the simulation increases.

IT'S YOUR FINANCIAL FUTURE aims to provide you with a trading strategy of outstanding possibilities. It is up to you to take advantage of it.
